

The Methodology Section

Penulisan Proposal (CCK4CAB2)

Course: Proposal Writing · Meeting 4 of 4 · Duration 100 minutes

01

What the Methodology Must Do

The section where vagueness is punished hardest.

Your methodology must prove that your **approach is clear, justified, and repeatable.**

What the Methodology Section Is

DEFINITION

The methodology is the section that turns your question into a procedure.
It states what data will be produced, from whom, by what means, and how those data will be analysed – in enough detail that another competent researcher could carry out the same study.

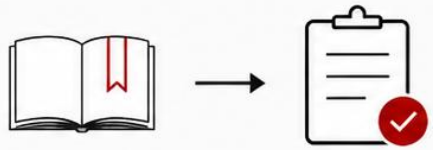

Replicable

Someone else could follow your steps and produce comparable data. If a step exists only in your head, it is not written yet.

Justified

Every choice is defended with a reason and, wherever possible, a precedent from the literature you reviewed.

Feasible

The plan can be executed with the time, access, budget, and skills you actually have this semester.

Key takeaway: Clarity + justification + feasibility = a methodology that earns trust.

Four Questions Your Reader Will Ask

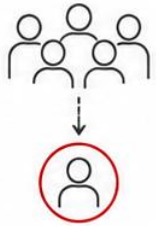

STANDARD OF DETAIL

Answer these with enough detail that another competent researcher could replicate your study.

1 From whom will the data come?

Define the population and how you will reach them.

- **Population**: who the results apply to
- **Sample**: who you will actually study
- **Selection**: how they will be chosen
- **Size**: how many and why
- **Reach**: how you will contact and include them

2 By what means will it be produced?

Specify the instrument or protocol in detail.

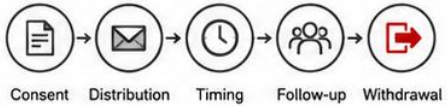

- **Instrument/Protocol**: name and version
- **Items/Steps**: list them clearly
- **Response format / Scale**: as used
- **Evidence**: why it measures what you claim

3 In what order will you act?

Lay out the procedure from start to finish.

- **Consent**: how and when
- **Distribution**: how materials/data are given
- **Timing**: when each step occurs
- **Follow-up**: reminders or additional contacts
- **Withdrawal**: what happens if someone leaves

4 How will the data become findings?

Explain exactly how you will analyse the data.

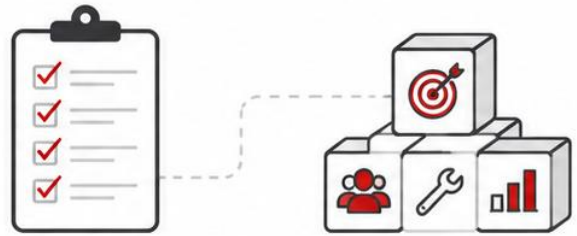

- **Analysis plan**: the techniques you will use
- **Data to be used**: which variables / sources
- **Purpose**: which question each analysis answers
- **Assumptions / Checks**: how you will verify results

Remember: Clarity, completeness, and precision now prevent doubts later.

Your goal: leave no room for "I'm not sure."

The Components and Their Jobs

ANATOMY OF THE SECTION

Component	What it must accomplish	Common heading
Research design	Names the overall approach and defends it against alternatives.	Research Design
Participants & sampling	Defines population, technique, size, and access.	Population and Sample
Instruments	Describes each tool and the evidence for its quality.	Research Instruments
Procedure	Sets out the steps from first contact to a complete data set.	Data Collection Procedure
Analysis plan	States the techniques applied to each type of data.	Data Analysis
Quality assurance	Validity and reliability, or trustworthiness in qualitative work.	Validity and Reliability
Ethics	Consent, confidentiality, approval, and risk to participants.	Ethical Considerations

Remember: Clarity, logic, and justification in each component allow others to replicate your study.

A research timeline, and a budget where the work is funded, usually follow this section.

Method, Methodology, and Approach

TERMINOLOGY

Three related terms that answer different questions in your study.

Approach

The broad stance toward evidence: what counts as knowledge in your study.

EXAMPLES

- Quantitative
- Qualitative
- Mixed methods

Methodology

The reasoned justification: why this design, sample, and instrument can answer your questions.

> *"A quasi-experimental design is appropriate because random assignment is not possible in intact classes."*

FOCUS: Provides the "why" — this is what earns marks.

Method

The concrete technique or tool you use to produce and treat data.

EXAMPLES

- A 24-item questionnaire
- Semi-structured interviews
- Thematic analysis

Remember: Most sections labelled "Methodology" in student proposals contain only methods. **The reasoning is the part that earns marks.**

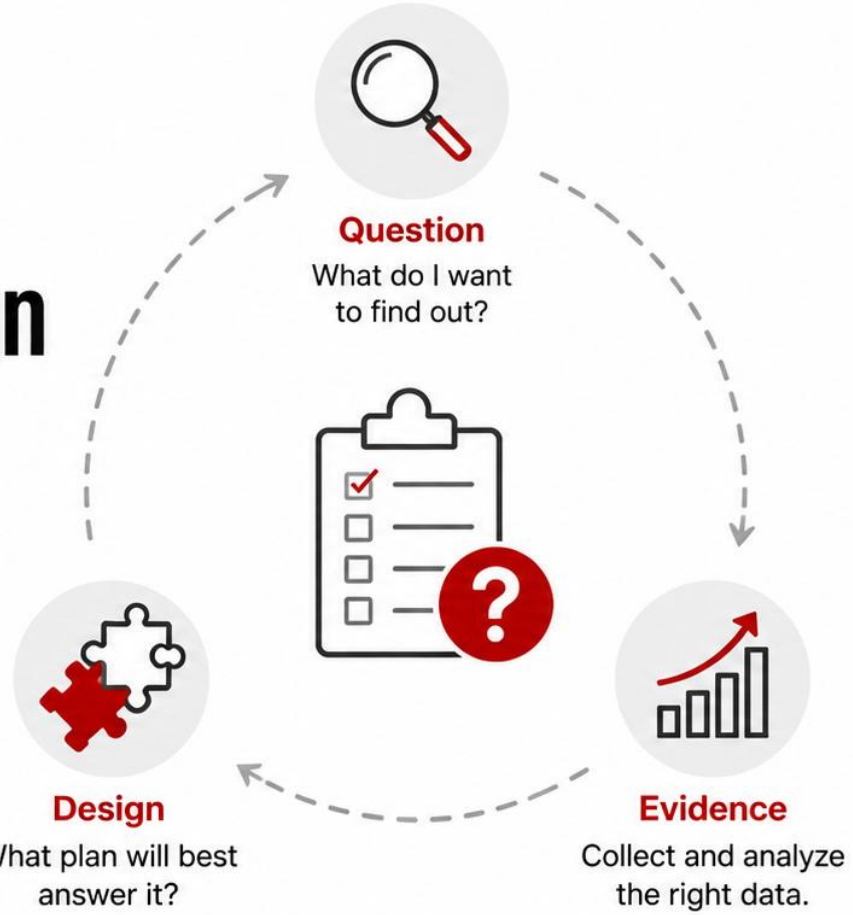

02

Choosing a Research Design

The design is **whatever can answer** the question you already committed to.

What it means:

Your research question comes first.
Your design is the plan that best answers it.

Three Broad Approaches

APPROACH

Each approach answers different kinds of questions and uses different kinds of evidence.

Quantitative

- Measures variables numerically
- Tests relationships or differences
- Larger samples, statistical analysis
- Aims for generalisation

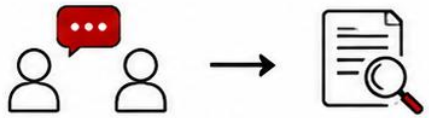

Answers: *how much, how many, how strongly, is there a difference.*

Qualitative

- Produces textual or visual data
- Interprets meaning and process
- Smaller, purposive samples
- Aims for depth and transferability

Answers: *how, why, what does this mean to participants.*

Mixed methods

- Combines both strands deliberately
- Requires a reason for combining
- States sequence and priority
- Integrates, not just reports both

Answers: *what happens, and why it happens that way.*

Remember: Mixed methods is not "both, to be safe". It doubles the work and must be justified by a question neither strand can answer alone.

Start with your research question. Let the question guide the design.

The Design Follows the Question

Start with a clear question. **The question determines** the data you need and the design you choose.

Start with your question → Decide what data you need → Choose the design that fits

If your question asks...	You need data that...	Typical design
How prevalent or how frequent something is	Describes a population numerically *Example: What percentage of students use AI tools weekly?*	**Descriptive survey**
Whether two variables move together	Measures both variables in the same people *Example: Is study time related to GPA?*	**Correlational**
Whether an intervention makes a difference	Compares groups before and after treatment *Example: Does a new teaching method improve test scores?*	**Experimental or quasi-experimental**
How people experience or interpret something	Captures accounts in participants' own words *Example: How do students experience online learning?*	**Phenomenology, case study, narrative**
How a process unfolds in one setting	Follows events and actors over time *Example: How does a startup build its culture over the first year?*	**Case study or ethnography**

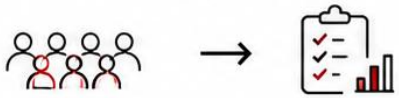

Remember: Work down this table with your own question before you read any further. **If no row fits, the question is still too vague.**

Common Quantitative Designs

Different designs answer different questions. **Choose the one** that best matches your research question.

Descriptive survey

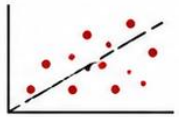

Measures the current state of variables in a population.
No manipulation, no causal claim.

Example: *What percentage of students use AI tools weekly?*

Correlational

Examines whether and how strongly variables move together. Association, never causation on its own.

Example: *Is study time related to GPA?*

Causal–comparative

Compares groups that already differ, looking backwards for an explanation of the difference.

Example: *Why are online learners' scores different?*

Quasi–experimental

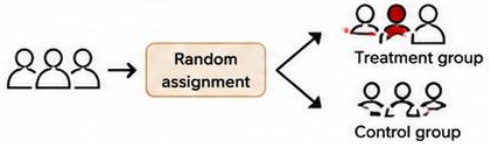

Compares treated and untreated intact groups. Common in education, where randomising classes is impossible.

Example: *Does a new teaching method improve test scores?*

True experimental

Random assignment to conditions with a controlled intervention. The strongest basis for causal claims.

Example: *Does the new method cause higher test scores?*

Longitudinal

Repeated measurement of the same participants over time. Powerful, and expensive in attrition.

Example: *How does motivation change during the first year of university?*

How to choose

Start with your question → Identify the data you need → Pick the simplest design that can answer it well.
If no design fits, refine your question.

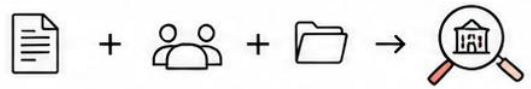

Tip Name your design with the term your field recognises and state in one sentence why it fits your question.

Common Qualitative Designs

These designs explore meaning, experience, and context. **Pick the one** that best fits your research question.

Case study

Investigates one bounded system in depth, using several data sources to understand it in context.

Example: A case study of student wellbeing in one university.

Phenomenology

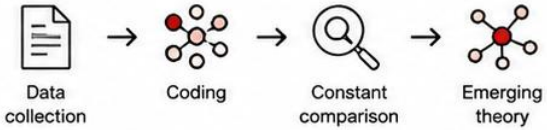

Describes the shared essence of how a group experiences one phenomenon, usually through in-depth interviews.

Example: Understanding first-year students' experience of online learning.

Grounded theory

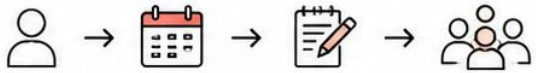

Builds a theory from the data through iterative coding and constant comparison.

Example: Developing a theory of academic resilience.

Ethnography

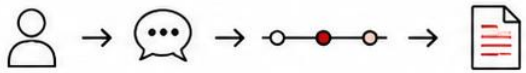

Studies a culture or community through prolonged engagement and observation in its own setting.

Example: An ethnography of classroom culture in a public school.

Narrative inquiry

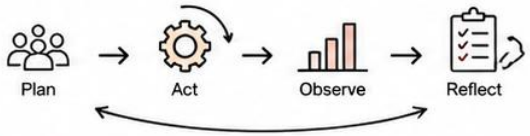

Analyses the stories individuals tell about their experience, keeping chronology and voice intact.

Example: The life stories of first-generation university students.

Action research

The researcher and participants change a practice together, studying the change as it happens.

Example: Improving tutoring practices through cycles of reflection and change.

Remember: Do not label your study "qualitative descriptive" by default.

Name the tradition, and follow its procedures.

Three Mixed-Methods Designs

Mixed methods combine the strengths of numbers and meaning. Choose the sequence that best fits your research question.

Convergent parallel

Both strands run at the same time, independently, and are compared at the interpretation stage.

Example
Survey students about satisfaction while also interviewing a subset, then compare the results to see where they agree or differ.

Use when you want measurement and meaning to corroborate one another.

Explanatory sequential

Quantitative first; qualitative afterwards to explain the results that were surprising or unclear.

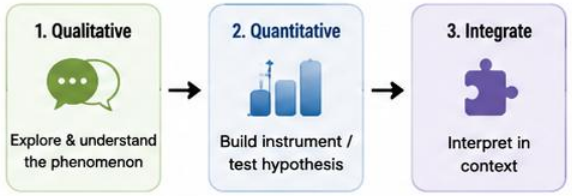

Example
Test the effect of a new learning method with a test. Then interview students to understand why some improved more than others.

Use when numbers show what happened but not why.

Exploratory sequential

Qualitative first; the findings then shape an instrument or hypothesis tested quantitatively.

Example
Interview teachers about challenges in online teaching. Use themes to build a survey and test how common each challenge is.

Use when no suitable instrument exists for your context.

Before you start
State: (1) the sequence, (2) the priority of each strand, and (3) the point at which the two are integrated.

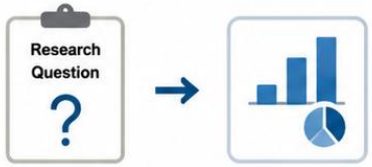

Example statement: *Explanatory sequential design: quantitative survey first, qualitative interviews second, integration during interpretation.*

Justifying Your Design

A strong justification shows your design is **logical**, **credible**, and the **best fit** for your research question.

1 Start from the question

Show that the data your design produces can, in principle, answer what you asked.

Example prompt

"How will this design generate data that answers my research question?"

2 Cite a precedent

Name studies in your literature review that used this design for a similar question.

Example prompt

"What similar studies used this design and what did they find?"

3 Rule out an alternative

Say briefly what you did not choose and why — this is what distinguishes a justification from an assertion.

Example prompt

"What other designs did I consider and why are they less suitable?"

4 Acknowledge what it cannot do

A correlational design cannot establish cause. Saying so protects you; hiding it invites the question.

Example prompt

"What are the limits of this design, and how will I be transparent about them?"

Four sentences, one per point, is usually enough — and more than most proposals manage.

03

Participants, Instruments, Procedure

From **whom**, by what **means**, and in what **order**.

Participants

Who will take part, how they will be selected, and how many.

Instruments

What tools or measures will be used to collect the data.

Procedure

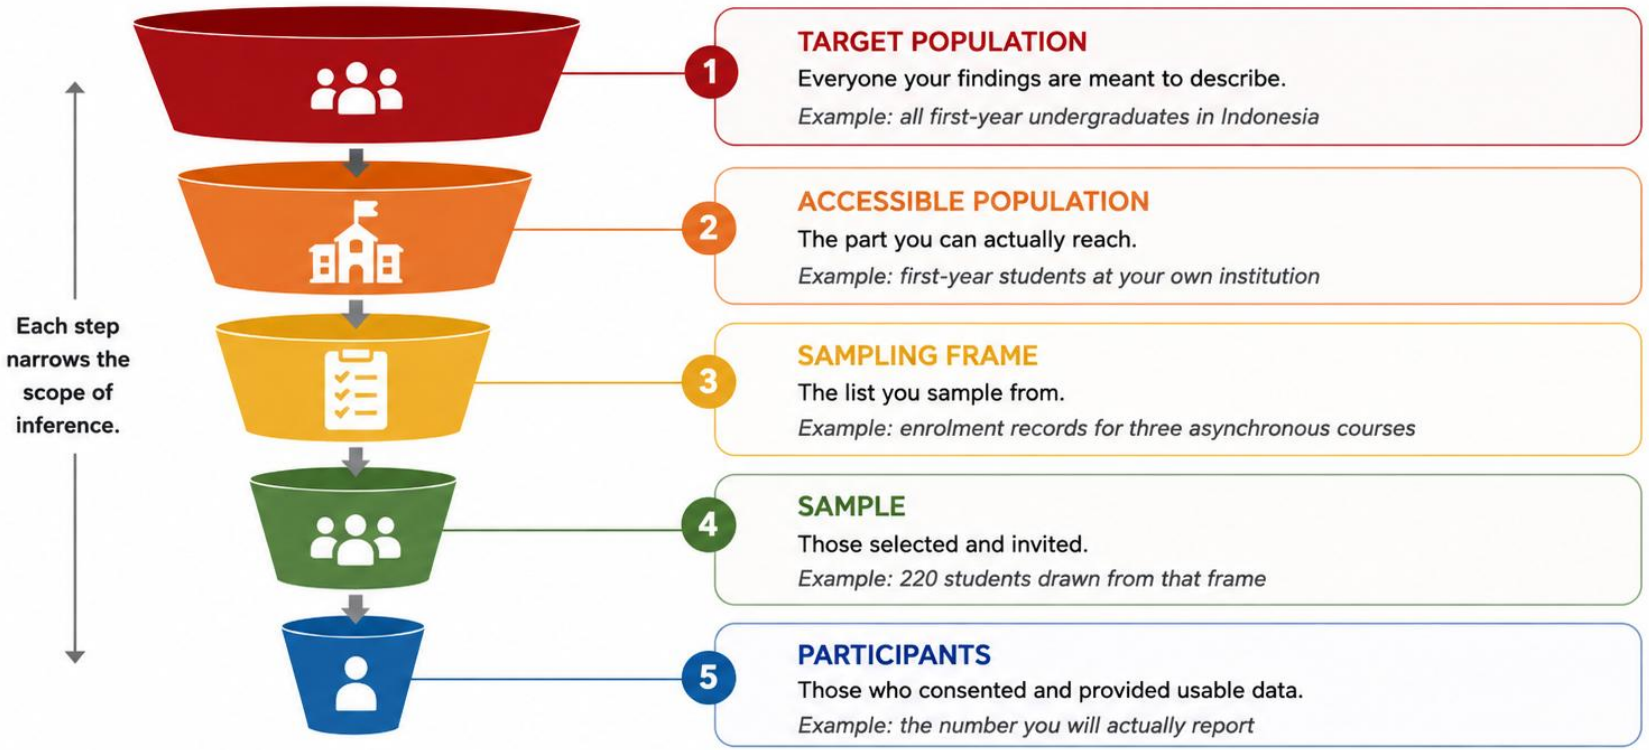

The step-by-step plan for collecting data, from start to finish.

*Clear **people**. Reliable **tools**. Logical **steps**.*

From Population to Sample

PARTICIPANTS

Each level narrows who your findings can legitimately speak about.

Generalisation stops at the accessible population. Claiming more than that is the most common overreach in student work.

Sampling Techniques

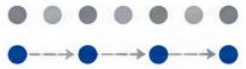

SELECTION

Different ways to choose who will be in your study.

PROBABILITY — EVERY UNIT HAS A KNOWN CHANCE

Simple random
Drawn at random from the full frame.

Systematic
Every kth unit from a randomly chosen start.

Stratified
Random within groups, preserving proportions.

Cluster
Whole groups sampled, then all or some units inside.

Supports statistical generalisation to the population, and is expected in most survey and experimental work.

NON-PROBABILITY — SELECTED FOR A REASON

Purposive
Chosen because they have the experience you study.

Convenience
Those available — state the limitation openly.

Quota
Fixed numbers per category, without randomisation.

Snowball
Participants recruit others, for hard-to-reach groups.

Standard in qualitative work, where the aim is depth and relevance rather than statistical representativeness.

Name the technique, state the criteria, and say how many. "Random" used loosely to mean "whoever replied" is a red flag.

How Many Participants?

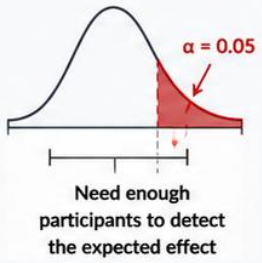

SAMPLE SIZE

The right size depends on your study, your goal, and the reality of your data collection.

1. Quantitative: justify the number

Base it on the analysis you plan — the number of groups or predictors, the effect you expect to detect, and the precision you need. Cite the rule or calculation you used.

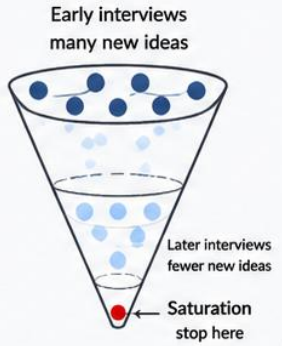

Example: Power analysis for multiple regression with 5 predictors, medium effect ($f^2 = 0.15$), power = 0.80, $\alpha = 0.05$ → minimum $n \approx 92$.

2. Qualitative: justify the depth

Size is judged by whether the data answer the question. Explain your reasoning, and report how you decided you had enough.

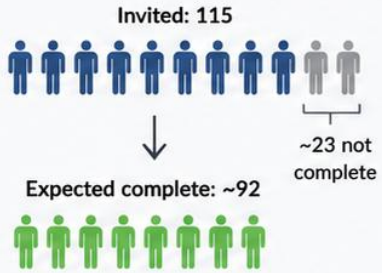

Example: Interviewed 18 students; no new themes emerged after the 15th interview (data saturation).

3. Plan for attrition

Some invitations are declined, some responses are incomplete, some participants withdraw. Recruit above your minimum.

Example: Need 92 complete surveys. Expect 20% non-response → invite at least 115 participants.

4. Defend it, do not guess it

"Thirty respondents, because that is a common number" is not a justification.

Any stated basis is better than none.

Whatever number you propose, write the sentence that begins "This number was chosen because...".
Clear reasoning builds trust in your study.

Instruments and What They Produce

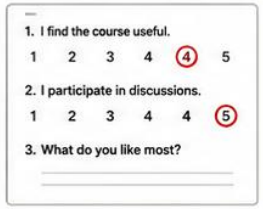

INSTRUMENTS

Different tools collect different kinds of data. Name it clearly, describe how it works, and include it in the appendix.

1. Questionnaire

Closed items produce numbers for statistical analysis; open items produce short text. State the scale and the number of items.

Produces:
Numeric data and/or short text responses.

2. Interview protocol

Structured, semi-structured, or unstructured. Attach the guide as an appendix, not a description of it.

Produces:
Detailed qualitative data in participants' own words.

3. Observation schedule

Records behaviour against defined categories or as field notes. Say who observes, when, and for how long.

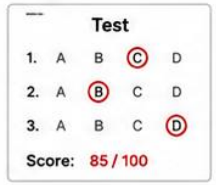

Produces:
Observed events, frequencies, or rich field notes.

4. Test or task

Produces performance data. Report how items were built or adopted, and how scores are calculated.

Produces:
Scores, accuracy, time, or task outcomes.

5. Documents and artefacts

Syllabi, records, policies, student work. Define the corpus and the period it covers.

Produces:
Textual or visual evidence for content analysis or document review.

6. System and log data

Platform analytics, timestamps, submission logs. Say who owns the data and how access is authorised.

Produces:
Behavioural traces and usage metrics.

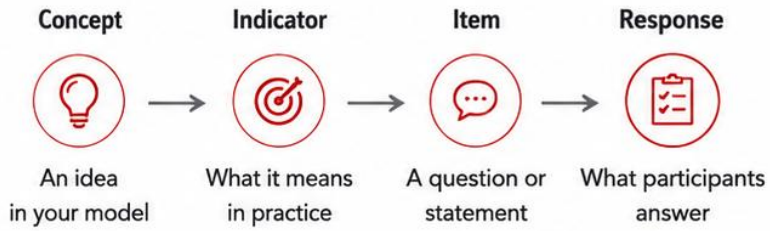

Every instrument you name must appear in full in an appendix.
A described instrument cannot be judged.

Turning Concepts Into Items

OPERATIONALISATION

Every variable in your framework must travel from concept to something a participant can actually respond to.

Variable (Concept)	Indicator (What it means)	Sample item (What participants answer)	Scale (How it's measured)	
Feedback timing	Perceived delay between submission and feedback	"I usually receive feedback in time to use it on the next task."	1 2 3 4 5 — Strongly disagree — Strongly agree	5-point agreement
Behavioural engagement	Participation in course activities	"I contribute to the discussion forum in most modules."	1 2 3 4 5 — Never — Very often	5-point frequency
Peer interaction	Exchanges with other students about coursework	"I discuss course tasks with other students during the week."	1 2 3 4 5 — Never — Very often	5-point frequency

Best practice: Adapting a published, validated instrument is almost always better than writing your own — cite the source, state what you changed, and report permission where it is required.

Validity and Reliability

QUALITY IN QUANTITATIVE WORK

Quality shows that your instrument measures the right thing, in the right way, consistently.

1. Content validity

The items cover the concept fully. Established by expert review against a blueprint.

Evidence: Expert panel review, content validity index (CVI).

2. Construct validity

The instrument measures the intended construct, shown by its relationships with other measures.

Evidence: Correlations with related constructs; factor analysis; known-groups comparison.

3. Criterion validity

Scores agree with an external standard, measured at the same time or later.

Evidence: Correlation with a gold standard or predictive validity for future outcomes.

4. Internal consistency

Items intended to measure one construct behave consistently together across respondents.

α Evidence: Cronbach's alpha ($\alpha \geq 0.70$ is acceptable).

5. Test–retest reliability

The same respondents produce similar scores when measured again after an interval.

Evidence: Correlation (e.g., r or ICC) between Time 1 and Time 2 scores.

6. Inter-rater reliability

Two independent raters classify the same material in the same way.

Evidence: Agreement statistics (e.g., Cohen's kappa, ICC).

Plan it in your timeline. State which types you will establish, how, and when (e.g., pilot study before main data collection). Pilot testing belongs in the timeline, not in a footnote.

Trustworthiness in Qualitative Work

QUALITY IN QUALITATIVE WORK

Trustworthiness shows your findings are believable, relevant, and dependable.
Use strategies that fit your design and report them clearly.

Collect data
Engage ethically and deeply

Analyse
Code and interpret systematically

Establish trustworthiness
Use the four criteria below

Report
Explain how each was addressed

1. Credibility

Do the findings represent what participants meant?

How to do it

- Member checking
- Prolonged engagement
- Triangulation of sources
- Peer debriefing

2. Transferability

Could a reader judge whether this applies elsewhere?

How to do it

- Thick description of context
- Clear description of participants
- Clear description of setting
- Purposeful sampling

3. Dependability

Would the process hold up to inspection?

How to do it

- Audit trail of decisions
- Documented methods
- Code–recode strategy
- External audit (if possible)

4. Confirmability

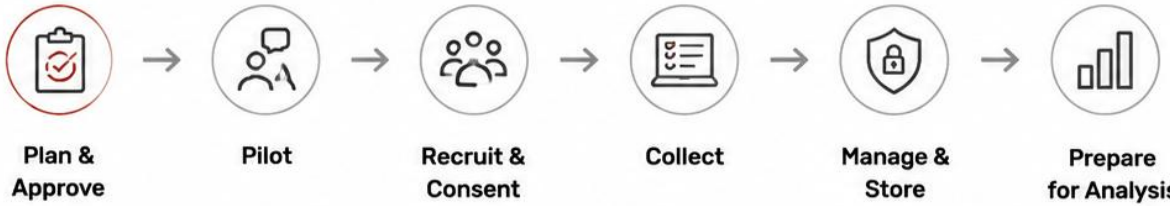

Are the findings grounded in data rather than in your assumptions?

How to do it

- Reflexivity (researcher journal)
- Documented coding
- Data extracts to support claims
- Independent review

Key reminder: Do not borrow the word “valid and reliable” for a qualitative design.
Use the criteria your tradition recognises, apply them consistently, and report how you did.

Writing the Procedure

DATA COLLECTION PROCEDURE

Written as a sequence a reader could follow.
Past tense in the report; future tense in the proposal.

1 Obtain approvals

Ethics clearance, institutional permission, and any gatekeeper consent, with dates.

Record approval IDs and dates.

2 Pilot the instrument

A small trial run to check wording, timing, and the analysis pipeline.

Document what was tested and the changes made.

3 Recruit and consent

How participants are invited, what they are told, and how consent is recorded.

Include inclusion/exclusion criteria.

4 Collect the data

When, where, in what form, and how long each session or response window lasts.

Specify tool/platform and mode (online, in-person, etc.).

5 Manage and store

Naming, anonymisation, storage location, access control, and retention period.

State who can access the data and for how long.

6 Prepare for analysis

Cleaning, transcription, coding of missing responses, and exclusion rules.

Define rules before analysing the data.

Good practice: Write in a clear sequence, use enough detail to replicate your steps, and report any deviations.

04

Analysis, Ethics, and Quality

How data become findings — and what protects the people who provided them.

ANALYSIS
Organize and interpret data to produce credible findings.

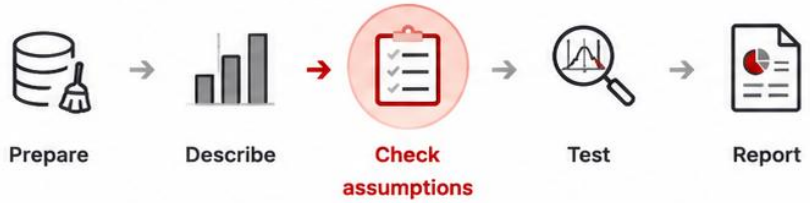

ETHICS
Respect, protect, and be accountable to participants.

QUALITY
Use trustworthy methods so findings are accurate and dependable.

Good research turns raw data into meaningful insights while upholding the highest standards of ethics and quality.

- Evidence-based
- Participant-centred
- Transparent and accountable

The Quantitative Analysis Plan

ANALYSIS

A clear plan turns your data into trustworthy answers to your research questions.

1 Prepare

- Clean the data.
- Handle missing responses by a stated rule.
- Reverse-score items where needed.

2 Describe

- Report distributions (histograms).
- Report means and standard deviations for every variable.
- Explore outliers.

3 Check assumptions

- Normality (e.g., Shapiro–Wilk, histogram, Q–Q plot).
- Homogeneity of variance (e.g., Levene's test).
- Independence of observations.
- Identify any assumption the planned test requires.

4 Test

- Apply the technique chosen in advance for each research question.
- State the significance level (e.g., $\alpha = .05$).
- Use appropriate post-hoc or follow-up tests if needed.

5 Report

- Present effect sizes (e.g., Cohen's d, η^2, r).
- Report confidence intervals.
- Report test statistics with df and p-values.
- Focus on meaning, not p-values alone.

Map every analysis to a research question **and name** the software you will use (e.g., SPSS, R, JASP, Jamovi).
A plan that does not map onto your questions is not a plan.

Matching Question to Technique

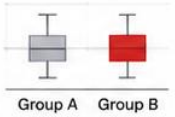

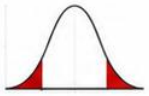

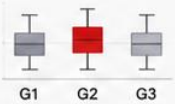

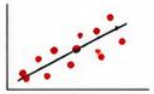

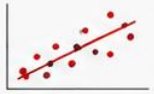

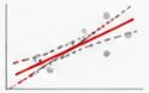

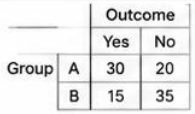

Start with your research question, look at your data, then choose the technique that fits.

1. Your question
What are you trying to find out?

2. Your data
What type of data do you have?

3. Choose technique
Pick the method that matches your data and question.

4. Test & report
Run the analysis and report clearly.

Your question	Your data	Commonly used technique (with example)
Do two independent groups differ?	 **One continuous outcome, two groups** *Example: Test scores of students in online vs face-to-face classes*	 **Independent-samples t-test, or a rank-based alternative** *Example: t-test*
Do three or more groups differ?	 **One continuous outcome, several groups** *Example: Satisfaction across three teaching methods*	 **One-way ANOVA, or a rank-based alternative** *Example: One-way ANOVA*
Do two variables move together?	 **Two continuous variables** *Example: Study time and exam score*	 **Pearson correlation, or Spearman for ranked data** *Example: Pearson correlation (r)*
Does one variable predict another?	 **One outcome, one or more predictors** *Example: Predicting GPA from study time and attendance*	 **Linear or multiple regression** *Example: Multiple linear regression*
Are two categories associated?	 **Two categorical variables** *Example: Gender (M/F) and course completion (Yes/No)*	 **Chi-square test of independence** *Example: χ^2 test*

Indicative only: the appropriate technique depends on your assumptions, design, and data.
Confirm your choice with your supervisor or a statistician before you collect anything.

The Qualitative Analysis Plan

ANALYSIS

Thematic analysis, shown here as the most widely used example. Whichever approach you use, name it and cite its source.

1 Familiarise

Transcribe, read repeatedly, and note first impressions before coding anything.

2 Code

Label segments systematically across the whole data set, keeping a codebook.

3 Search for themes

Group codes into candidate themes that say something about the question.

4 Review and define

Check themes against the data, merge or discard, and name each one precisely.

5 Report

Write the account, evidenced with quotations that are attributed and anonymised.

State **who codes**, whether a **second coder** is involved, and how **disagreements** are resolved.

Name the approach used (e.g., Braun & Clarke, 2006) and cite the source.

Ethics in the Methodology

NON-NEGOTIABLES

Ethics protect participants, strengthen your study, and build trust in your findings.

1 Approval before collection

Obtain ethics clearance and institutional permission before collecting any data.

Describe the approval process and include dates.

Shows oversight and accountability from the start.

2 Informed consent

Tell participants the purpose, what is asked of them, risks (if any), benefits, and that they may withdraw at any time without penalty.

Ensures participation is voluntary and informed.

3 Confidentiality and anonymity

Remove identifiers (names, IDs, contact details). State where data are stored, who has access, and when data will be destroyed.

Protects privacy and complies with data policies.

4 Care with vulnerable groups

Minors, patients, employees, and your own students need extra safeguards and, where required, guardian consent.

Reduces risk of harm or undue influence.

5 Power and coercion

Do not pressure or imply consequences for saying no. Participation must never be linked to grades, jobs, or services.

Prevents perceived pressure and preserves dignity.

6 Tools and data handling

Do not upload identifiable participant data to external or public AI tools or services. Follow your institution's policy on AI and data handling.

Minimises risk from third-party platforms.

A study that would be ethical only if nobody checked is not ethical.
Write this section as if it will be audited.

The Research Timeline

PLANNING

An indicative twelve-week schedule. Yours should match your own calendar, including approval waiting time.

Task	Week 1	2	3	4	5	6	7	8	9	10	11	12
Ethics approval and permissions			Build in time for review and approval									
Instrument preparation and pilot					Refine after pilot before full launch							
Data collection									Collect enough quality data			
Data analysis										Clean, code, and analyse		
Writing the findings											Draft results and discussion	
Revision and submission												Revise and submit

Ethics approval is the step students underestimate most.
Ask your department how long it actually takes, and schedule backwards from your deadline.

Where Methodologies Fail

COMMON FAILURES

Clear methods make your study credible, replicable, and ethical.

1 

Too vague to repeat

"Data will be analysed thematically" with no procedure, coder, software, or framework named.

Why it's a problem: Others cannot repeat your steps or trust your findings.

2 

Design does not fit the question

Interviews proposed for a question about prevalence, or a survey for a question about lived experience.

Why it's a problem: The method cannot produce the evidence your question needs.

3 

Sampling described loosely

"Random sampling" used to describe whoever happened to respond to a broadcast link.

Why it's a problem: Not truly random; introduces bias and limits generalisability.

4 

Instrument neither cited nor attached

A questionnaire mentioned in the text but absent from the appendices and unattributed.

Why it's a problem: Readers cannot review items, scales, or validity of measures used.

5 

No quality evidence

No validity, reliability, or trustworthiness strategy, and no plan for establishing any.

Why it's a problem: Unclear if your findings are credible or dependable.

6 

Ethics reduced to one sentence

"Ethical principles will be observed" — with no consent process, storage plan, or approval route.

Why it's a problem: Does not show how participants' rights and wellbeing are protected.

Good methods = clear, justified, and verifiable. Give enough detail so another researcher could follow your steps.

Methodology Checklist

BEFORE YOU SUBMIT THE DRAFT

Use this checklist to make sure your methodology is clear, rigorous, and easy to replicate.

1. **The design is named, justified, and linked to the research questions**
   State the design type (e.g., cross-sectional survey) and explain why it fits your questions.

2. **Population, sampling technique, size, and access are all stated**
   Specify who, how, how many, and how you will gain access.

3. **Each instrument is described, sourced, and attached as an appendix**
   Provide the name, source (with citation), key sections, and include the instrument.

4. **Variables are operationalised: concept, indicator, item, and scale**
   Define each variable clearly and show how it will be measured.

5. **Validity and reliability — or trustworthiness — strategies are specified**
   Explain steps to ensure quality (e.g., pilot test, Cronbach's alpha, member checking, triangulation).

6. **The procedure reads as steps another researcher could follow**
   Write in sequence: what, where, when, how, by whom, and for how long.

7. **The analysis plan names techniques and maps them to each question**
   State the technique for each question and the software you will use.

8. **Ethics covers approval, consent, confidentiality, storage, and risk**
   Describe approvals, consent process, data handling, storage location, retention, and potential risks.

Quick test: Give this section to someone outside your topic and ask them to describe what you will do.
What they cannot repeat is not written clearly enough.

Five Things to Remember

KEY TAKEAWAYS

1 The question chooses the design

Not familiarity, not convenience, and not what your friend used last semester.

2 Replicability is the standard

Write so that a competent stranger could carry out your study without asking you anything.

3 Justify, do not merely describe

Every choice needs a reason, a precedent, and an acknowledged limitation.

4 Quality evidence is part of the plan

Validity, reliability, or trustworthiness must be designed in, not claimed afterwards.

5 Ethics is written before data exists

Approval, consent, and storage are planned in the proposal, never retrofitted.

Thank You

That completes the four-week series. Good luck with your proposals.

Week 4 of 4 · Research Proposal Writing
